ATTY. DOCKET NO.: PHNL 020233

METHOD AND DEVICE FOR PERFORMING TILT CORRECTION
USING MULTI-DIMENSIONAL ACTUATOR

BACKGROUND OF THE INVENTION

Field Of The Invention

[0001] The present invention relates to a tilt control device and method for correcting tilt of a recording surface of an optical disc, such as, for example, a recordable or read-only disk, by using a multi-dimensional actuator, e.g., a 3D actuator.

[0002] In recent years, optical disc apparatuses have been developed for recording and reproducing large quantities of data.

[0003] Principally, an optical disc should be kept in a flat disc shape when it is set on a disc motor, so that an optical pickup unit can keep its optical axis perpendicular to the recording surface of the disc during recording and reproducing operations. For scanning the recording tracks, the optical pickup unit moves in a radial direction in alignment with the radius of the optical disc.

[0004] However, the optical disc set on the disc motor is not flat, mainly due to the manufacturing process. The optical disc curves both in the radial and circumferential directions. Furthermore, all kinds of drive tolerances may be faced. Therefore, the optical pickup unit cannot scan the recording tracks with its optical axis perpendicular to the recording surface of the disc. Furthermore, the angle varies according to the position of the

optical pickup unit with respect to the optical disc. The angle formed between the optical axis and the recording surface in a radial direction is defined as the radial tilt angle. Additionally, the angle formed between the optical axis and a line tangential to the recording track (or perpendicular to the radius) of the optical disc is referred to as the tangential tilt. Generally, the amount of radial tilt of the optical disc is within a range of $\pm 10\text{mrad}$

[0005] The user data is extracted from the HF signal. Due to, e.g., time errors in the HF signal, a certain amount of jitter is always present when reading out an optical disc. Some contributors for such a jitter are intersymbol interference, crosstalk between neighboring tracks and disc manufacturing imperfections, but also ordinary noise, present in all electrical circuits. The tilt angle between the disc and the objective lens, is a result of two major contributors, namely, the disc (contribution by manufacturing tolerances and environmental changes) and the drive (contribution by objective lens actuator, turntable motor adjustment, axis adjustment, etc.). The resulting angular deviations lead to comatic aberrations, i.e., a distortion of the optical readout spot on the disc. This distorted readout spot directly results in a distorted HF signal and thus in timing errors, i.e., jitter. Generally, the jitter increases at a greater rate as the radial tilt becomes larger.

[0006] Tighter system tolerances in systems like DVD and DVD+RW require decreased maximal allowed tilt errors. These maximal

allowed tilt errors are specified in a tilt window which can be, e.g., ± 8 mrad in the radial direction. This tilt window is defined to achieve a jitter below a certain required level (typically 15%). If the total tilt in the readout system is larger than this window, the jitter will be too high and active tilt compensation is required. Therefore, in order to reproduce the original signal from the recording track under such fluctuation factors, it is necessary to adjust the optical disc apparatus with respect to the physical fluctuations, such as radial tilt and/or tangential tilt.

10

Description Of The Related Art

[0007] Japanese Patent Publication No. JP-A-2000-195080

discloses a conventional optical disc apparatus in which a tilt control is applied. In operation, tilt detection means outputs a tilting signal having a voltage corresponding to the tilting amount of the optical disc with respect to an optical head used for recording and reproducing. The tilt control means drives the tilt actuating means or radial tilt adjuster such that a tilt control signal becomes zero. Thus, the optical head can be kept in a position parallel to the optical disc so that a signal with a good quality can be recorded thereto or reproduced therefrom.

[0008] Furthermore, International Patent Application No. WO-A-00/16321, corresponding to U.S. Patent 6,157,600, discloses a tilt control device and method, wherein a sledge of an optical pickup unit is placed on a tilting unit which can tilt or incline in the

25

radial direction with respect to the optical disc. In response to a change in the radial tilting angle, the angle of the optical axis of the pickup unit changes with respect to the recording surface of the disc. As a result, the jitter of the signal reproduced also
5 varies.

[0009] The tilt sensor may be calibrated on the basis of a jitter measurement in a predetermined calibration data track area. In response to a change in the radial tilting angle, the angle of the optical axis of the pickup unit, with respect to the recording
10 surface of the disc, also changes. As a result, the jitter of the signal reproduced from the calibration data track also changes. The position at which the jitter of the reproduced signal shows its smallest value is the optimum position for the radial tilt. However, a sensor calibration based on the jitter is not possible
15 for non-written optical discs, such as DVD+RW discs.

[0010] To reduce costs, the tilt sensor can be omitted. The tilt measurement may then be based on the dz/dr method, wherein the DC components of the radial tilt are measured using the actuator of the optical reading system. In particular, the DC radial tilt is
20 measured through differentiation of the DC actuator voltage, i.e., the mean actuator voltage over one disc revolution, to the radius r , times the DC sensitivity of the actuator. However, this tilt measurement is very sensitive to the focus DC sensitivity and, therefore, has to be calibrated. Such a calibration can easily be
25 performed in drives with a tilting frame. Unfortunately, this

calibration is not possible for drives that use a 3D actuator to compensate tilt.

SUMMARY OF THE INVENTION

5 [0011] It is, therefore, an object of the present invention to provide a tilt control device and method by means of which an accurate sensorless tilt measurement can be provided with a 3D actuator.

[0012] This object is achieved by a tilt control device for
10 controlling a radial tilt of a recording surface of an optical disc with respect to an optical recording/reproducing beam, said tilt control device comprising control means for generating two focus controlling outputs; and actuating means for controlling a focusing state of the optical recording/reproducing beam based on said two
15 focus controlling outputs and the radial tilt, characterized in that said control means is arranged to determine the radial tilt value based on a differentiation of focus control values obtained at different radii of said optical disk..

[0013] Accordingly, the specific multi-dimensional actuator
20 design is used in combination with a dz/dr tilt measurement to provide an improved accuracy for sensorless tilt measurements. The combination of, e.g., a 3D actuator with the dz/dr tilt measurement provides the advantage that focus and tilt adjustment can be performed in the same element. Thereby, influences or measurement
25 variations caused by environmental conditions and/or circuit

characteristics can be minimized to reduce compensations requirements.

[0014] Preferably, the actuator design is based on a splitting of focus coils. Thereby, the actuator tilt DC sensitivity can be directly related to the focus DC sensitivity, and the sensor sensitivity is cancelled out by the tilt compensator sensitivity. Now, the actuator can be used for feed-forward tilt compensation without offset or gain errors and without any additional sensor, and a very accurate tilt control functionality can be achieved.

10

BRIEF DESCRIPTION OF THE DRAWINGS

[0015] The invention will now be described on the basis of a preferred embodiment with reference to the accompanying drawings, in which:

15 [0016] Fig. 1 shows a basic block diagram of a tilt control device according to the preferred embodiment;

[0017] Fig. 2 shows a schematic arrangement of a 3D actuator which can be applied in the preferred embodiment;

20 [0018] Fig. 3 shows a schematic block diagram indicating control parts for generating voltages applied to the 3D actuator;

[0019] Fig. 4 shows a diagram indicating different radial positions and corresponding different focus positions measured during initialization to determine mean radial tilt;

[0020] Fig. 5 shows a diagram indicating different radial positions and corresponding mean tilt values applied during a tracking operation; and

[0021] Fig. 6 indicates a flow diagram of a tilt control method
5 according to the preferred embodiment.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

[0022] The preferred embodiment will now be described on the basis of a tilt control operation in an optical disc player.

10 [0023] In Fig. 1, a tilt control arrangement or device is shown for correcting tilt with respect to an optical disc 1. The tilt control device comprises an optical pickup unit comprising a movable carriage or sledge 4 for moving the optical pickup unit in a radial direction on a platform 5. The optical pickup unit
15 comprises an optical head 2 which directs and receives a radiation beam to/from the optical disc 1 through a 3D actuator 11 arranged to control the focus, tilt and radial position of the 3D actuator by a three-dimensional actuating function based on split focus coils. Each of the split focus coils of the 3D actuator 11 is
20 driven based on an own focus control signal received from a processor 10.

[0024] Furthermore, a focus evaluator 6 is provided which produces a focusing error signal based on a beam reflection signal obtained of the optical head 2. According to the preferred
25 embodiment, the mean radial disc tilt is initially measured by

means of the mean focus voltages at different radii on the disc 1. To achieve this, the mean radial tilt between two radii is calculated and stored in the controller 10, and the calculated mean tilt is then used to generate or calculate a tilt control output
5 signal used for controlling the 3D actuator during a disc tracking operation.

[0025] Fig. 2 shows a more detailed schematic diagram of the arrangement of the 3D actuator 11. In Fig. 2, the 3D actuator is attached to the sledge 4 by spring arrangements S1 to S3 thereby
10 allowing three-dimensional movement of the 3D actuator 11 with respect to the sledge 4 and the recording surface of the optical disc 1. Thereby, the point at which the radiation beam impinges on the recording surface of the optical disc 1 and the impinging angle of the radiation beam with respect to the recording surface can be
15 controlled. The radiation beam is directed between the optical head 2 and the optical disc 1 via a mirror 41 and an objective lens 110. The optical head 2 comprises a radiation source (not shown), e.g., a laser, for generating the radiation beam, e.g., laser beam, and a detector (not shown) for receiving light reflected from the
20 recording surface of the optical disc 1 and guided back to the optical head 2 via the objective lens 110 and the mirror 41. Based on the reflected light signals detected at the optical head 2, radial and focus tracking error signal may be generated.

[0026] Furthermore, the 3D actuator 11 comprises split focus
25 coils C1, C2 for controlling focus and tilt, and a radial coil Cr

for controlling the radial position of the 3D actuator 11. The split focus coils are arranged at respective radial distances a_1 and a_2 , respectively, from a central symmetry line of the 3D actuator 11. When a voltage is applied to the coils and the coils are arranged in a magnetic field, each of the split focus coils C_1 , C_2 and the radial coil C_r generates an own force F_{f1} , F_{f2} and F_r , respectively, depending on the current I flowing through the coil windings. The force generated by each of the coils can be calculated based on the known Lorentz equation:

$$F = kI \quad [N/A] \quad (1)$$

Thus, the factor k indicates the amount of force generated due to a current I . Due to the eccentric arrangement of the split focus coils C_1 and C_2 , a tilt β can be generated if $F_{f1} = -F_{f2}$, while a vertical movement (z direction) along the symmetry line perpendicular to the surface of the optical disc 1 can be generated if $F_{f1} = F_{f2}$.

[0027] Fig. 3 shows a schematic block diagram indicating control parts for generating control voltages U_{f1} , U_{f2} and U_r each applied, e.g., between one end of the respective actuator coil and a ground terminal or other fixed reference voltage, based on control data stored in respective control registers R_f , R_β and R_r , or any other kind of memory. The control parts may be arranged at the processor 10 or a separate control device provided at the 3D actuator 11.

[0028] In particular, focus control data r_f obtained from the focus evaluator 6 and processor 10 (based on, e.g., a PID (Proportional Integral Derivative) controller function), is stored in a focus control register R_f , tilt control data r_β is stored in a tilt control register R_β and radial control data r_r is stored in a radial control register R_r . The actuator coils C_1 , C_2 and C_r may be arranged in a star connection as indicated in Fig. 3. A radial control voltage U_r for controlling the radial coil C_r is generated by inputting the radial control data r_r into digital/analog converter (DAC) having a gain G_{da3} and supplying the converted analog signal to a power amplifier or end stage having a gain GE_3 . Additionally, focus control voltages U_{f1} and U_{f2} are generated based on a predetermined combination of the focus control data r_f and the tilt control data r_β . Particularly, a first focus control voltage U_{f1} is generated by adding the focus control data r_f and the tilt control data r_β and supplying the result via a dedicated DAC having a gain G_{da1} to a dedicated power end stage having a gain GE_1 . Moreover, a second focus control voltage U_{f2} is generated by subtracting the tilt control data r_β from the focus control data r_f and supplying the result via a dedicated DAC having a gain G_{da2} to a dedicated power end stage having a gain GE_2 . Thus, the focus, tilt and radial position of the 3D actuator 11 can be controlled by storing control data in the control registers R_f , R_β and R_r . If the focus control data r_f and the tilt control data r_β is selected such that $U_{f1} = -U_{f2}$, a tilt β is applied to the 3D actuator 11. On the

other hand, if the focus control data r_f and the tilt control data r_β is selected such that $U_{f1} = U_{f2}$, a z movement is generated at the 3D actuator 11. The focus control data r_f and the radial control data r_r may be controlled by a conventional PID controller, while the tilt control data r_β may be controlled by a feed-forward algorithm using a tilt table in which mean tilt values are stored.

[0029] For the 3D actuator design according to the preferred embodiment, the following feed-forward algorithm can be used which is highly invariant to the focus and tilt DC sensitivity variations, and any end-stage and digital-to-analog conversion gain variations.

[0030] Based on focus control values obtained from the focus evaluator 6 at the different radii, the mean radial disc tilt can be calculated using the following equation (2):

$$\beta_m = G_{DC;focus} G_{dac} \frac{\Delta r_f}{\Delta R} \quad (2)$$

where Δr_f is the difference between two averaged focus control data values measured during initialization, ΔR is the sledge step in radial direction between two measurements, G_{dac} is the gain of the DAC combined with the power end stage in the feed-forward control path indicated in Fig. 3, and $G_{DC;focus}$ is the focus DC sensitivity (in m/V) of the 3D actuator 11. The measurement result is linear dependent on the generally unknown focus DC sensitivity.

[0031] To compensate disc tilt with the 3D actuator 11, the control data r_β of the tilt register control register R_β must be calculated in accordance with the following equation (3):

$$r_\beta = \frac{G_c \beta_d}{G_{DC;tilt} G_{dac}}$$

(3)

where β_d is the mean disc tilt of the disc 1, G_c is the factor between actuator tilt and disc tilt for which comatic aberrations are optimal corrected, G_{dac} is the gain of the DAC combined with the power end stage of the feed-forward control path, and $G_{DC;tilt}$ is the tilt DC sensitivity (in rad/V) of the 3D actuator 11. The actual resulting actuator tilt is dependent on the generally unknown tilt DC sensitivity.

[0032] Substitution of the measured mean disc tilt β_m in equation (2) for the actuator disc tilt β_d of equation (3), leads to the following equation (4):

$$r_\beta = \frac{G_c G_{DC:focus} \Delta r_f}{G_{DC;tilt} \Delta R}$$

(4)

[0033] If both DC sensitivities (focus and tilt) are known, the 3D actuator 11 can be controlled accurately in tilt direction based on the measured mean focus control data (Δr_f) and sledge step (ΔR).

[0034] In general, both DC sensitivities are dependent on the magnetic field and the coil resistance of the actuator coils. Both quantities fluctuate from batch to batch and as a function of

temperature, and, therefore, introduce a lot of errors preventing the use of feed-forward open-loop control with a 3D actuator.

However, if an actuator is used where tilt actuating is performed by means of splitting the focus coils, as in the 3D actuator 11, it can be shown that both effects strongly cancel each other. For the 3D actuator 11 shown in Fig. 2, the focus and tilt DC sensitivities can be expressed as follows:

$$G_{DC, focus} = \frac{k_f}{c_f R_f} \quad (5)$$

and

$$G_{DC, tilt} = \frac{k_f(a_1 + a_2)}{c_t R_f} \quad (6)$$

where k_f denotes the k-factor of the split focus coils C1 and C2, R_f denotes the ohmic resistance of the split focus coils C1 and C2, c_f denotes the spring constant of the springs S1 and S2 with respect to a z-movement of the 3D actuator 11, and c_t denotes the spring constant of the springs S1 and S2 with respect to a tilt movement of the 3D actuator 11.

[0035] Substitution of these sensitivities in the expression for the tilt register value r_β leads to

$$r_\beta = \frac{G_c c_f \Delta r_f}{c_f(a_1 + a_2) \Delta R} \quad (7)$$

which is completely independent of the coil resistance R_f and actuator focus k-factor (magnetic field) and, therefore, independent of temperature and batch variations. Geometrical deviations, such as (a_1+a_2) , are considered to be limited and only
5 deviations between focus stiffness and torsion stiffness influence the gain errors.

[0036] It is noted that no offset error is present in this tilt control scheme.

[0037] Even for actuators with strongly varying focus k-factors
10 as a function of the vertical z-position (focus), the measurement error and the compensation error cancel each other. For example, at a nominal position of $z=+0.6$ mm the focus k-factor may have dropped by a factor two. Thus, a factor two, higher coil voltages are required to focus the actuator leading to a measured disc tilt β_m
15 of two times the result in the $z=0$ position. Accordingly, the tilt actuator set point equals twice the set point obtained at the $z=0$ position. However, due to the fact that the tilt DC sensitivity has also dropped by a factor two at $z=+0.6$ mm, the actuator is controlled to the required disc tilt β_d .

20 [0038] In the following, the tilt control procedure according to the preferred embodiment is described with reference to Figs. 4 to 6.

[0039] Fig. 4 shows a diagram schematically indicating different focus positions z_1 to z_3 of the 3D actuator 11 at corresponding
25 radial positions R_1 to R_3 on a tilted recording surface of the

optical disc 1. During initialization, in a first step S200 of Fig. 6, the mean focus values are obtained from the controller function (e.g., PID output) of the processor 10 at a plurality of different radii (e.g., R_1 to R_3) of the optical disc 1. Then, based on
 5 equation (2), a mean radial disc tilt value β_{mi} is derived in step S201 between two radial positions R_i from the focus control data r_f , e.g., mean focus values obtained from the controller function of the processor 10, wherein Δr_f corresponds to the difference in the focus control values between two radial positions R_i and R_{i+1} .
 10 Then, in step S202, the obtained mean radial tilt values β_{mi} are then stored, e.g., in a tilt table which may be arranged as follows:

radial positions	mean disc tilt values
$(R_1+R_2)/2$	β_{m1}
$(R_2+R_3)/2$	β_{m2}

15 As indicated in Fig. 5, the stored mean tilt values β_{mi} are then applied during a subsequent tracking (read or write) operation to control the tilt angle of the 3D actuator 11 (step S203 in Fig. 6). To achieve this, tilt control data r_β corresponding to the stored mean tilt value may be obtained based
 20 on one of the equations (3), (4) and (7). Interpolation can be used for positions between selected radii.

[0040] As an alternative, the tilt control data r_{β} , may be directly stored in the tilt table. Thus, angular deviations between the objective lens 110 and the recording surface of the optical disc 1 can be removed substantially. It is noted that measurements
5 have to be performed at least at two radii R_i . After initial measurement of the radial disc geometry and start-up, the disc geometry should remain constant, e.g., in the order of 0.1mm and 1 mrad, over a time span required to write or read one entire disc.

[0041] The combination of the above described dz/dr tilt
10 measurement and feed-forward tilt steering with the 3D actuator 11 provides a promising solution to the problem of accuracy in sensorless tilt measurements with 3D actuators.

[0042] The present invention is applicable for any type of disc, including all types of recordable discs. Thus, various
15 modifications may become apparent to those skilled in the art, without departing from the scope of the invention, as defined in the claims. The invention is applicable to any optical recording and reproducing device having any kind of multi-dimensional actuator with a split coil arrangement arranged to control focus
20 and tilt. Thus, even a two-dimensional type of actuator allowing control only in the radial plane may be used for the present invention.
